#### Abstract

A density functional theory investigation on the geometrical and electronic properties of $\mathrm{B}_{4} 5_{2}^{0 /-/ 2-}\left(\mathrm{B}_{2}(\mathrm{BS})_{2}^{0 /-/ 2-}\right)$ and $\mathrm{B}_{5} \mathrm{~S}_{4}^{0 /-}\left(\mathrm{B}(\mathrm{BS})_{4}^{0-}\right)$ clusters has been performed in this work. Both the doublet $\mathrm{B}_{2}(\mathrm{BS})_{2}^{-}\left([\mathrm{S}=\mathrm{B}-\mathrm{B}=\mathrm{B}-\mathrm{B}=\mathrm{S}]^{-}\right)\left(\mathrm{D}_{\infty \mathrm{h}}{ }^{2} \Pi_{\mathrm{u}}\right)$ and the singlet $\mathrm{B}_{2}(\mathrm{BS})_{2}^{2-}\left([\mathrm{S}=\mathrm{B}-\mathrm{B}=\mathrm{B}-\mathrm{B}=\mathrm{S}]^{2-}\right)\left(\mathrm{D}_{\infty \mathrm{h}}{ }^{1}{ }^{1} \Sigma_{\mathrm{g}}^{+}\right)$proved to have perfect linear ground-state structures containing a multiply bonded $B B$ core ( $B \equiv B$ or $B \equiv B$ ) terminated with two $B S$ groups, while $T_{d} B(B S)_{4}^{-}$turned out to possess a perfect $B^{-}$tetrahedral center directly corrected to four BS groups, similar to the corresponding boron hydride molecules of $\mathrm{D}_{\propto h} \mathrm{~B}_{2} \mathrm{H}_{2}^{-}, \mathrm{D}_{\infty h} \mathrm{~B}_{2} \mathrm{H}_{2}^{2-}$, and $\mathrm{T}_{\mathrm{d}} \mathrm{BH}_{4}^{-}$, respectively. $\mathrm{B}_{4} \mathrm{~S}_{2}$ and $\mathrm{B}_{5} \mathrm{~S}_{4}$ neutrals, however, appeared to be much different: they favor a planar fan-shaped $C_{2 v} B_{4} S_{2}$ (a di-S-bridged $\mathrm{B}_{4}$ rhombus) and a planar kite-like $\mathrm{C}_{2 \mathrm{v}} \mathrm{B}_{5} \mathrm{~S}_{4}$ (a di-S-bridged $\mathrm{B}_{3}$ triangle bonded to two BS groups), respectively. One-electron detachment energies and symmetrical stretching vibrational frequencies are calculated for $D_{\infty h} B_{2}(B S)_{2}^{-}$and $T_{d}$ $\mathrm{B}(\mathrm{BS})_{4}^{-}$monoanions to facilitate their future characterizations. Neutral salts of $\mathrm{B}_{2}(\mathrm{BS})_{2} \mathrm{Li}_{2}$ with an elusive $\mathrm{B} \equiv \mathrm{B}$ triple bond and $\mathrm{B}(\mathrm{BS})_{4} \mathrm{Li}$ containing a tetrahedral $\mathrm{B}^{-}$center are predicted possible to be targeted in experiments. © 2009 Wiley Periodicals, Inc. [^0]
## 1. Introduction

Boron oxide clusters $\mathrm{B}_{\mathrm{x}} \mathrm{O}_{\mathrm{y}}$ have attracted considerable attention in recent years because of their importance in both fundamental research and materials sciences. In four recent articles [1-4], Zhai, Yao, Li, and Wang performed combined photoelectron spectroscopy (PES) and ab initio theory investigations on a series of boron oxide clusters in gas phases, including the linear $\mathrm{C}_{\infty \mathrm{v}} \mathrm{BO}^{-}$and $\mathrm{D}_{\infty h} \mathrm{BO}_{2}^{-}$[1], linear $\mathrm{D}_{\infty \mathrm{h}} \mathrm{B}(\mathrm{BO})_{2}^{-}$ and triangular $\mathrm{D}_{3 \mathrm{~h}} \quad \mathrm{~B}(\mathrm{BO})_{3}^{-} \quad[2]$, linear $\mathrm{D}_{\infty h}$ $\mathrm{B}_{2}(\mathrm{BO})_{2}^{0 /-/ 2-}$ [3], and tetrahedral $\mathrm{T}_{\mathrm{d}} \mathrm{B}(\mathrm{BO})_{4}^{-}$[4]. These studies confirmed the existence of BO groups (boronyls) and $B B$ multiple bonds ( $B=B$, $B \equiv B$, and $B \equiv B$ ) in a wide range of boron oxide clusters and revealed a clear structural link between boron oxide clusters $\mathrm{B}_{m}(\mathrm{BO})_{n}$ and the corresponding boron hydride molecules $\mathrm{B}_{m} \mathrm{H}_{n}$. Recent theoretical studies performed by other groups well support this conclusion [5, 6]. Considering the similarities between $S\left(3 s^{2} 3 p^{4}\right)$ and $\mathrm{O}\left(2 s^{2} 2 p^{4}\right)$ in valence electron configurations, our group performed recently a density functional theory (DFT) investigation on linear $\mathrm{BS}^{-}, \mathrm{BS}_{2}^{-}$, and $\mathrm{B}(\mathrm{BS})_{2}^{-}$and triangular $\mathrm{B}(\mathrm{BS})_{3}^{-}$[7]. Close similarities were obtained between BS and $\mathrm{BO} \sigma$ radicals and $\mathrm{B}(\mathrm{BS})_{n}^{0 /-}$ and $\mathrm{B}(\mathrm{BO})_{n}^{0 /-}(n=2,3)$ microclusters. However, there have been no experimental or theoretical investigations on $\mathrm{B}_{m}(\mathrm{BS})_{n}$ clusters with $m>1$ or $n>3$ reported in literature $[7,8]$. In this work, we extend the research at ab initio levels to novel boron sulfide clusters including $\mathrm{B}_{4} \mathrm{~S}_{2}^{0 /-/ 2-}\left(\mathrm{B}_{2}(\mathrm{BS})_{2}^{0 /-/ 2-}\right)$ and $\mathrm{B}_{5} \mathrm{~S}_{4}^{0 /-}\left(\mathrm{B}(\mathrm{BS})_{4}^{0 /-}\right)$ at different charged states. Both $\mathrm{D}_{\infty} \quad \mathrm{B}_{2}(\mathrm{BS})_{2}^{-}$monoanion ( $[\mathrm{S}=\mathrm{B}-\mathrm{B} \equiv \mathrm{B}-\mathrm{B}=\mathrm{S}]^{-}$) and $\mathrm{D}_{\infty h} \mathrm{~B}_{2}(\mathrm{BS})_{2}^{2-}$ dianion ( $[\mathrm{S}=\mathrm{B}-\mathrm{B} \equiv \mathrm{B}-\mathrm{B}=\mathrm{S}]^{2-}$ ) turned out to possess perfect linear ground-state structures containing a multiply bonded BB core ( $B \equiv B$ or $B \equiv B$ ) terminated with two $B S$ groups, while $\mathrm{B}(\mathrm{BS})_{4}^{-}$proved to have a perfect tetrahedral geometry with a $\mathrm{B}^{-}$center directly bonded to four BS groups, similar to the corresponding boron hydride molecules of $\mathrm{D}_{\infty h} \mathrm{~B}_{2} \mathrm{H}_{2}^{-}, \mathrm{D}_{\infty h} \mathrm{~B}_{2} \mathrm{H}_{2}^{2-}$, and $\mathrm{T}_{\mathrm{d}} \mathrm{BH}_{4}^{-}$, respectively. However, the ground states of their neutrals proved to be much different: $\mathrm{B}_{4} \mathrm{~S}_{2}$ favored a planar fan-shaped $\mathrm{C}_{2 \mathrm{v}}$ structure (a di-Sbridged $B_{4}$ rhombus), while $B_{5} S_{4}$ possessed a planar kite-like $C_{2 v}$ geometry (a di-S-bridged $B_{3}$ triangle connected to two BS groups). These molecular fragments could be relevant for matrix spectroscopy or possibly in mass spectroscopy of boron
sulfide solids. As B-S binary compounds were more volatile than their $\mathrm{B}-\mathrm{O}$ analogies and investigation of their structures and thermodynamic properties was believed to be greatly facilitated [8], the boron sulfide clusters theoretically studied in this work are expected to be synthesized and characterized in future experiments.

## 2. Computational Methods

DFT structural optimizations and frequency analyses of boron sulfide clusters were performed using the hybrid B3LYP procedure [9] with the Dunning's all-electron basis (aug-cc-pVTZ) [10] implemented in Gaussian 03 program [11]. Extensive structure searches have been performed on these small clusters to determine their groundstate structures, starting from either the geometries of the corresponding boron oxide clusters [3, 4] without symmetry constrains or arbitrarily designed initial structures with specific symmetries. Energy refinements were achieved using the coupled cluster method including triple excitations (CCSD $(\mathrm{T})$ ) [12] at the B3LYP structures with the same basis to determine the relative stabilities of the low-lying isomers more accurately. Adiabatic detachment energies (ADEs) were calculated as the energy differences between the anions and the corresponding neutrals at their ground-state structures, while the vertical detachment energies (VDEs) as the energy differences between the anions and their neutrals at the ground-state structures of the anions. One-electron detachment energies of the monoanions were also approximated with the outer valence Green function approach (OVGF(full)) [13]. Figure 1 shows the ground-state structures of linear $\mathrm{B}_{2}(\mathrm{BS})_{2}^{-/ 2-}$ and the fan-shaped $\mathrm{B}_{4} \mathrm{~S}_{2}$. Figure 2 depicts the lowlying isomers of $\mathrm{B}_{4} \mathrm{~S}_{2}^{0 /-92-}$ at different charged states. Figure 3 illustrates the $\pi$ and $\sigma$ BB multiple bonding within the $\mathrm{B}_{2}$ cores and the $\mathrm{B}-\mathrm{B} \sigma$ single bonds between the $B_{2}$ core and the two $B S$ terminals in linear $\mathrm{B}_{2}(\mathrm{BS})_{2}^{0 /-/ 2-}$. Figure 4 shows the transition state of $\mathrm{D}_{2 \mathrm{~h}} \mathrm{~B}_{4} \mathrm{~S}_{2} \mathrm{Li}_{2}$ and the ground state of $\mathrm{C}_{2 \mathrm{~h}} \mathrm{~B}_{4} \mathrm{~S}_{2} \mathrm{Li}_{2}$ which contain a $\mathrm{B} \equiv \mathrm{B}$ triple bond at the center. Figure 5 depicts the ground-state structures of tetrahedral $\mathrm{T}_{\mathrm{d}} \mathrm{B}(\mathrm{BS})_{4}^{-}$, tetrahedral $\mathrm{T}_{\mathrm{d}}$ $\mathrm{C}(\mathrm{BS})_{4}$, the $\mathrm{Li}^{+}$-bridged $\mathrm{C}_{2 \mathrm{v}} \mathrm{B}_{5} \mathrm{~S}_{4} \mathrm{Li}$, and the planar kite-like $B_{5} S_{4}$, while Figure 6 shows the low-lying isomers of $\mathrm{B}_{5} \mathrm{~S}_{4}^{0 /-}$. The four $\mathrm{B}-\mathrm{B} \sigma$ orbitals of $\mathrm{T}_{\mathrm{d}} \mathrm{B}(\mathrm{BS})_{4}^{-}$are illustrated in Figure 7. Table I summarizes the calculated electronic properties and

Linear triplet $B_{2}(B S)_{2}$ is also shown for comparison. [Color figure can be viewed in the online issue, which is available at wileyonlinelibrary.com.]
symmetrical stretching vibrational frequencies of the most concerned high symmetry clusters. Table II tabulates the calculated one-electron detachment energies of $\mathrm{D}_{\infty \mathrm{h}} \mathrm{B}_{2}(\mathrm{BS})_{2}^{-}$and $\mathrm{T}_{\mathrm{d}} \mathrm{B}(\mathrm{BS})_{4}^{-}$.

## 3. Results and Discussion

## 3.1. $\mathbf{B}_{\mathbf{2}}(\mathrm{BS})_{2}^{-}, \mathbf{B}_{\mathbf{2}}(\mathbf{B S})_{2}^{\mathbf{2 -}}$, AND $\mathbf{B}_{4} \mathbf{S}_{\mathbf{2}}$

We start from boron sulfide anions possible to be observed in PES experiments first. As can be seen from Figures 1 and 2, analogous to $\mathrm{D}_{\infty \mathrm{h}}$ $\mathrm{B}_{2}(\mathrm{BO})_{2}^{-}$and $\mathrm{D}_{\infty \mathrm{h}} \mathrm{B}_{2}(\mathrm{BO})_{2}{ }^{2-3}$, both the ground states of doublet $D_{\infty h} B_{2}(B S)_{2}^{-}\left({ }^{2} \Pi_{u}\right)$ and singlet $\mathrm{D}_{\infty \mathrm{h}} \mathrm{B}_{2}(\mathrm{BS})_{2}^{2-}\left({ }^{1} \Sigma_{\mathrm{g}}^{+}\right)$possess a perfect linear geometry (1) lying at least 0.38 and 0.78 eV lower than other low-lying isomers (2-8). For $\mathrm{B}_{4} \mathrm{~S}_{2}^{-}$monoanion, $C_{2 v} 2$ and $C_{2 v} 6$ both contain an S- or SBSbridged $B_{3}$ triangle [14], while all other low-lying isomers ( $3,4,5,7$, and 8 ) possess a rhombus $\mathrm{B}_{4}$ core [14] with S bridges or S terminals. $\mathrm{B}_{4} \mathrm{~S}_{2}^{2-}$ dia-
nion possesses similar low-lying structures in a different energy order. However, unlike $\mathrm{B}_{4} \mathrm{O}_{2}$ which has a clear linear triplet ground state $[\mathrm{O}=\mathrm{B}-\mathrm{B}=\mathrm{B}-\mathrm{B}=\mathrm{O}][3]$, the ground state of $\mathrm{B}_{4} \mathrm{~S}_{2}$ neutral turned out to be the planar fan-shaped $C_{2 v} 7\left({ }^{1} \mathrm{~A}_{1}\right)$ (a di-S-bridged rhombus $\left.\mathrm{B}_{4}\right)$, with the linear triplet $D_{\infty h} \mathrm{~B}_{2}(\mathrm{BS})_{2}\left(1,{ }^{3} \Sigma_{\mathrm{g}}^{-}\right)$serving as a local minimum lying 0.55 eV higher in energy. In fact, both the di-S-bridged $\mathrm{C}_{2 \mathrm{v}} \mathrm{B}_{4} \mathrm{~S}_{2}$ (4) and $\mathrm{C}_{2 \mathrm{v}}$ $\mathrm{B}_{4} \mathrm{~S}_{2}$ (8) also lay lower than linear $\mathrm{D}_{\infty h} \mathrm{~B}_{2}(\mathrm{BS})_{2}(1)$ by 0.18 eV and 0.34 eV , respectively. Concerning the bond length variations in the optimized linear $[S=B-B=B-B=S]^{0 /-/ 2-}$ chains, it is interesting to notice that, with the molecular net charges increasing from $0,-1$, to -2 , the BB multiple bond lengths within the $\mathrm{B}_{2}$ core decease from $1.522 \AA, 1.497 \AA$, to $1.491 \AA$, the $B-B$ single bonds between the $B_{2}$ core and BS groups decrease from $1.600 \AA, 1.584 \AA$, to $1.569 \AA$, while the $B-S$ distances within the BS groups increase from 1.614 $\AA, 1.647 \AA$, to $1.694 \AA$ (see Fig. 1). This situation is very similar to that observed in $\mathrm{B}_{2}\left(\mathrm{BO}_{2}\right)_{2}^{0 /-/ 2-}$

FIGURE 2. Low-lying isomers obtained $\mathrm{B}_{4} \mathrm{~S}_{2}^{0 /-/ 2-}$ clusters in the increasing energy order of $\mathrm{B}_{4} \mathrm{~S}_{2}^{-}$, with energies relative to the linear $1(\Delta E, \mathrm{eV})$ indicated at $\operatorname{CCSD}(\mathrm{T}) / / \mathrm{B} 3 \mathrm{LYP}$ level. The lowest vibrational frequencies $\left(V_{\text {min }}, \mathrm{cm}^{-1}\right)$ and the number of imaginary frequencies (quoted in parentheses) are also indicated at B3LYP. Notice, the first, second, and the third numbers stand for $\mathrm{B}_{4} \mathrm{~S}_{2}, \mathrm{~B}_{4} \mathrm{~S}_{2}^{-}$, and $\mathrm{B}_{4} \mathrm{~S}_{2}^{2-}$, respectively. [Color figure can be viewed in the online issue, which is available at at wileyonlinelibrary.com.]

FIGURE 3. Pictures of the selected occupied molecular orbitals responsible for the BB multiple bonds within the $\mathrm{B}_{2}$ cores and the $B-B$ single bonds between $B_{2}$ core and the two $B S$ terminals in linear $D_{\infty h} B_{2}(B O)_{2}^{0 /-/ 2-}$. [Color figure can be viewed in the online issue, which is available at wileyonlinelibrary.com.]
series (3), confirming the existence of formal $B=B, B \equiv B$, and $B \equiv B$ multiple bonds in linear $\mathrm{B}_{2}(\mathrm{BS})_{2}^{0 /-/ 2-}$ series and further supporting the isolobal relationship between $-\mathrm{H},-\mathrm{BO}$, and -BS groups [7].

As mentioned earlier, the di-S-bridged $\mathrm{C}_{2 \mathrm{v}} \mathrm{B}_{4} \mathrm{~S}_{2}$ (4), $C_{2 v} B_{4} S_{2}$ (7), and $C_{2 v} B_{4} S_{2}$ (8) all turned out to be more stable than linear $\mathrm{B}_{2}(\mathrm{BS})_{2}(\mathbf{1})$, with $\mathrm{C}_{2 \mathrm{v}}$ $\mathrm{B}_{4} \mathrm{~S}_{2}$ (7) being the global minimum of the neutral. Other low-lying $\mathrm{B}_{4} \mathrm{~S}_{2}$ neutral isomers (2, 3, 5, 6) with bridging or terminal BS group(s) or a bridging SBS group appeared to lie at least 0.22 eV higher than $D_{\infty h} B_{2}(B S)_{2}(\mathbf{1})$. Bridging $S$ atoms are favored over $B S$ groups in $B_{4} S_{2}$ neutral isomers which prefer to contain a rhombus $\mathrm{B}_{4}$ core. This situation is different from $\mathrm{B}_{4} \mathrm{O}_{2}$ which clearly favors the linear triplet $\mathrm{D}_{\infty h} \mathrm{~B}_{2}(\mathrm{BO})_{2}$ containing a $\mathrm{B}_{2}$ core terminated with two BO groups [3], in line with the fact that a BS group possesses a lower bond energy ( $132 \mathrm{Kcal} / \mathrm{mol}$ at B3LYP) than that ( $194 \mathrm{Kcal} / \mathrm{mol}$ ) of a BO group.

The linear structures of $[\mathrm{S}=\mathrm{B}-\mathrm{BB}-\mathrm{B}=\mathrm{S}]^{0 /-/ 2-}$ series originate from the triplet ground state of the $B_{2}$ core $\left({ }^{3} \Sigma_{g}^{-}\right)$[14] and the $\sigma$ radical nature of the two terminal BS groups [7] and can be understood in terms of the unique orbital occupations of the linear systems (see Fig. 3). The triplet low-lying linear $[\mathrm{S}=\mathrm{B}-\mathrm{B}=\mathrm{B}-\mathrm{B}=\mathrm{S}]\left({ }^{3} \Sigma_{\mathrm{g}}^{-}\right)$ possesses the valence electronic configuration of $1 \sigma_{\mathrm{g}}^{2} 1 \sigma_{\mathrm{u}}^{2} 2 \sigma_{\mathrm{g}}^{2} 2 \sigma_{\mathrm{u}}^{2} 3 \sigma_{\mathrm{g}}^{2} 3 \sigma_{\mathrm{u}}^{2} 4 \sigma_{\mathrm{g}}^{2} 1 \pi_{\mathrm{u}}^{4} 1 \pi_{\mathrm{g}}^{4} 2 \pi_{\mathrm{u}}^{2}$. The halffilled degenerate HOMOs $\left(2 \pi_{\mathrm{u}}\right)$ and the fully occupied HOMO-3 $\left(4 \sigma_{\mathrm{g}}\right)$ mainly contribute to the
$B=B$ double bond interaction which has the formal bond order of 2 , while the doubly occupied HOMO-6 $\left(2 \sigma_{\mathrm{u}}\right)$ and HOMO-7 $\left(2 \sigma_{\mathrm{g}}\right)$ form the two $\mathrm{B}-\mathrm{B} \sigma$ single bonds between $\mathrm{B}_{2}$ core and the two BS terminal groups. With one or two extra electrons successively added into the degenerate HOMOs $\left(2 \pi_{\mathrm{u}}\right), \quad[\mathrm{S}=\mathrm{B}-\mathrm{B} \equiv \mathrm{B}-\mathrm{B}=\mathrm{S}]^{-}$monoanion $\left({ }^{2} \Pi_{\mathrm{u}}: 1 \sigma_{\mathrm{g}}^{2} 1 \sigma_{\mathrm{u}}^{2} 21 \sigma_{\mathrm{g}}^{2} 2 \sigma_{\mathrm{u}}^{2} 3 \sigma_{\mathrm{g}}^{2} 3 \sigma_{\mathrm{u}}^{2} 4 \sigma_{\mathrm{g}}^{2} 1 \pi_{\mathrm{u}}^{4} 1 \pi_{\mathrm{g}}^{4} 2 \pi_{\mathrm{u}}^{3}\right)$ and $[\mathrm{S}=$ $\mathrm{B}-\mathrm{B} \equiv \mathrm{B}-\mathrm{B}=\mathrm{S}]^{2-}$ dianion $\left({ }^{1} \Sigma_{\mathrm{g}}^{+}: 1 \sigma_{\mathrm{g}}^{2} 1 \sigma_{\mathrm{u}}^{2} 21 \sigma_{\mathrm{g}}^{2} 2 \sigma_{\mathrm{u}}^{2} 3 \sigma_{\mathrm{g}}^{2}\right.$ $3 \sigma_{\mathrm{u}}^{2} 4 \sigma_{\mathrm{g}}^{2} 1 \pi_{\mathrm{u}}^{4} 1 \pi_{\mathrm{g}}^{4} 2 \pi_{\mathrm{u}}^{4}$ ) possess the formal BB bond orders of 2.5 and 3 within the $B_{2}$ core, respectively. With the bond orders increasing from 2, 2.5 , to 3 , the BB multiple bond lengths within the $B_{2}$ core decrease gradually from $D_{\infty h} B_{2}(B S)_{2}$, $\mathrm{D}_{\infty h} \mathrm{~B}_{2}(\mathrm{BS})_{2}^{-}$, to $\mathrm{D}_{\infty h} \mathrm{~B}_{2}(\mathrm{BS})_{2}^{2-}$ (see discussion above). However, the bond length decreasing of $0.006 \AA$ from $B \equiv B$ in $[S=B-B \equiv B-B=S]^{-}$to $B \equiv B$ in $[S=B-B \equiv B-B=S]^{2-}$ is obviously too small.

Coulomb repulsion in the highly charged $[S=B-B \equiv B-B=S]^{2-}$ dianion partially cancels the $B \equiv B$ covalent triple bond and eventually makes the calculated $\mathrm{B} \equiv \mathrm{B}$ bond length slightly longer $(0.03 \AA)$ than the expected value of $r_{\mathrm{B} \equiv \mathrm{B}}=1.46 \AA$ [15]. This situation can be effectively changed by introducing two $\mathrm{Li}^{+}$countercations into $\mathrm{B}_{2}(\mathrm{BS})_{2}^{2-}$ dianion to form a $\mathrm{B}_{2}(\mathrm{BS})_{2} \mathrm{Li}_{2}$ neutral, as shown in Figure 4. The transition state of $\mathrm{D}_{2 \mathrm{~h}} \mathrm{~B}_{2}(\mathrm{BS})_{2} \mathrm{Li}_{2}$ $\left({ }^{1} \mathrm{~A}_{\mathrm{g}}\right)$ (with an imaginary vibrational frequency of

$-52 \mathrm{~cm}^{-1}$ ) lies 0.09 eV higher than the distorted ground state of $C_{2 h} B_{2}(B S)_{2} L_{2}\left({ }^{1} \mathrm{~A}_{\mathrm{g}}\right)$ and the $\mathrm{B} \equiv \mathrm{B}$ triple bond lengths in these neutral structures are reduced to $1.46-1.47 \AA . \mathrm{B}_{2}(\mathrm{BS})_{2} \mathrm{Li}_{2}$ salt is predicted possible to be synthesized in experiments to prepare the elusive $\mathrm{B} \equiv \mathrm{B}$-containing compounds [3]. It should also be mentioned that, similar to the $\mathrm{B} \equiv \mathrm{O}$ triple bonds discussed in our previous articles [13], the calculated $\mathrm{B}-\mathrm{S}$ bond lengths between 1.61 and $1.69 \AA$ in the $\mathrm{B}_{2}(\mathrm{BO})_{2}^{0 /-/ 2-}$ series within the BS groups (see Fig. 1) turned out to be quite close to the expected $B \equiv S$ triple bond lengths of $1.68 \AA$ [15].

Natural bonding orbital analyses further help to qualitatively understand the bonding situation in $[S=B-B B-B=S]^{0 /-/ 2-}$ linear chains. The Wiberg bond indexes (WBI) of BB multiple interactions within the $\mathrm{B}_{2}$ cores increase from $\mathrm{WBI}_{\mathrm{BB}}=1.40$, 1.78, to 2.06 from linear $\mathrm{B}_{2}(\mathrm{BS})_{2}, \mathrm{~B}_{2}(\mathrm{BS})_{2}^{-}$, to $\mathrm{B}_{2}(\mathrm{BS})_{2}^{2-}$, with the corresponding total bond orders of the central B atoms increasing from $\mathrm{WBI}_{\mathrm{B}}=$ $2.65,3.26$, to 3.88 . These values qualitatively support the BB multiple bond length decreasing discussed above. Interestingly, the bond orders of the $B-B$ interactions between the $B_{2}$ core and the two $B S$ groups also increase from $\mathrm{WBI}_{\mathrm{B}-\mathrm{B}}=1.13,1.23$, and 1.37, indicating that these $B-B$ interactions possess certain double bond characteristics (especially in $\mathrm{B}_{2}(\mathrm{BS})_{2}^{2-}$ in which the $\mathrm{B}-\mathrm{B}$ bond length possesses the lowest value of $1.569 \AA$ ). This agrees with the observation that the HOMO $\left(\pi_{\mathrm{u}}\right)$ of the systems has been partially delocalized along the $B_{4}$ chains at the centers of the $[S=B-B B-B=S]^{0 /-/ 2-}$ structures (see Fig. 3).

## 3.2. $\mathbf{B ( B S})_{4}^{-}{ }^{-}$AND $\mathbf{B}_{\mathbf{3}} \mathbf{S}_{\mathbf{4}}$

Similar to the geometries of $\mathrm{T}_{\mathrm{d}} \mathrm{BH}_{4}^{-}$and $\mathrm{T}_{\mathrm{d}}$ $\mathrm{B}(\mathrm{BO})_{4}^{-}[4], \mathrm{B}_{5} \mathrm{~S}_{4}^{-}$anion proved to have a perfect
tetrahedral ground state of $\mathrm{T}_{\mathrm{d}} \mathrm{B}(\mathrm{BS}){ }_{4}^{-}\left(9,{ }^{1} \mathrm{~A}_{1}\right)$, in which the four BS groups were directly connected to the negatively charged $B$ center, with the $B-B$ bond lengths of 1.648 A and $\mathrm{B}=\mathrm{S}$ bond lengths of $1.632 \AA$ (see Figs. 5 and 6). Replacing the negative $B$ center in 9 with a $C$ atom produces the $T_{d}$ $\mathrm{C}(\mathrm{BS})_{4}$ neutral $\left({ }^{1} \mathrm{~A}_{1}\right)$ which is a BS substitute of $\mathrm{CH}_{4}$ with the bond lengths of $r_{\mathrm{C}-\mathrm{B}}=1.545 \AA$ and $r_{\mathrm{B}=\mathrm{S}}=1.603 \AA$. Other 2 D and $3 \mathrm{D} \mathrm{B}_{5} \mathrm{~S}_{4}^{-}$isomers (10-16) analogous to the low-lying isomers of $\mathrm{B}_{5} \mathrm{O}_{4}^{-}$[4] lie at least 0.91 eV higher than $\mathrm{T}_{\mathrm{d}}$ $\mathrm{B}(\mathrm{BO})_{4}^{-}$(9), suggesting that a $\mathrm{B}^{-}$tetrahedral center is strongly favored in a $\mathrm{B}(\mathrm{BO})_{4}^{-}$anion. The results obtained here on $\mathrm{T}_{\mathrm{d}} \mathrm{B}(\mathrm{BS})_{4}^{-}$and $\mathrm{T}_{\mathrm{d}} \quad \mathrm{C}(\mathrm{BS})_{4}$ strongly support the $\mathrm{B}^{-} / \mathrm{C}$ analog noticed in our previous work [4]. A perfect squared $D_{4 h} B_{5} S_{4}^{-}$ (with a planar tetracoordinate B at the center) similar to the ground state of $\mathrm{D}_{4 \mathrm{~h}} \mathrm{Al}_{5} \mathrm{O}_{4}^{-}$[16]

proved to lie very higher in energy ( $>15 \mathrm{eV}$ ). Introducing a bridging $\mathrm{Li}^{+}$cation to $\mathrm{T}_{\mathrm{d}} \mathrm{B}(\mathrm{BO})_{4}^{-}$ produces the $\mathrm{Li}^{+}$-bridged $\mathrm{C}_{2 \mathrm{v}} \mathrm{B}(\mathrm{BO})_{4} \mathrm{Li} \quad\left({ }^{1} \mathrm{~A}_{1}\right)$ which is the global minimum of the neutral (see Fig. 5). Tetrahedral B center is well maintained in $\mathrm{C}_{2 \mathrm{v}} \mathrm{B}(\mathrm{BO})_{4} \mathrm{Li}$ ion-pair, suggesting the possibility of synthesizing $\mathrm{B}(\mathrm{BO})_{4} \mathrm{Li}$ salt containing tetrahedral $\mathrm{B}^{-}$centers in experiments.

Given the BS/H isolobal relationship [4], the high stability of tetrahedral $\mathrm{T}_{\mathrm{d}} \mathrm{B}(\mathrm{BS})_{4}^{-}$can be understood in its molecular orbitals shown in Figure 7 which represent the four $\mathrm{B}-\mathrm{B} \sigma$ bonds between the B center and its BS ligands. In fact, the electronic configuration of $\mathrm{B} 2 s^{0.95} 2 p^{3.68}$ in $\mathrm{T}_{\mathrm{d}} \quad \mathrm{B}(\mathrm{BS})_{4}^{-}$anion qualitatively agrees with $\mathrm{C} 2 s^{1.17} 2 p^{4.28}$ in $\mathrm{T}_{\mathrm{d}} \mathrm{C}(\mathrm{BS})_{4}$ neutral, indicating that the $B$ center in $T_{d} B(B S)_{4}^{-}$with the negative atomic charge of $q_{\mathrm{B}}=-1.69$ |e| behaves similar to the $C$ center in $T_{d} C(B S)_{4}$ which has the net charge of $q_{C}=-1.54 \quad|e|$. The calculated $B-B$ bond order of $\mathrm{WBI}_{\mathrm{B}-\mathrm{B}}=0.93$ and the total bond order of the central B atom $\mathrm{WBI}_{\mathrm{B}}=3.93$ well support the $B \operatorname{sp}^{3}$ hybridization pattern in $\mathrm{T}_{\mathrm{d}} 9$.

Detaching one electron from the perfect tetrahedral $\mathrm{T}_{\mathrm{d}} \mathrm{B}(\mathrm{BS})_{4}^{-}(15)$ involves a John-Teller process to produce the severely distorted local minimum of $C_{2} B(B S)_{4}$ (see Fig. 5) which lies 1.49 eV higher than the ground state of the neutral system—a planar kite-like $\mathrm{C}_{2 \mathrm{v}} \mathrm{B}_{5} \mathrm{~S}_{4}\left(11,{ }^{2} \mathrm{~B}_{1}\right) . \mathrm{C}_{2 \mathrm{v}} \mathrm{B}_{5} \mathrm{~S}_{4}$ contains a di-S-bridged $B_{3}$ triangle [14] bonded to two BS groups. All the other low-lying isomers of $\mathrm{B}_{5} \mathrm{~S}_{4}$ shown in Figure 6 also proved to be more stable than $C_{2} B_{5} S_{4}$, indicating that a tetrahedral $B$ center directly bonded to four $B S$ groups in $B_{5} S_{4}$ neutral is extremely unstable. $\mathrm{C}_{2 \mathrm{v}} \quad \mathrm{B}_{5} \mathrm{~S}_{4} \quad$ (11) appeared to be also much different from the ground state of the Y -shaped $\mathrm{C}_{\mathrm{s}} \mathrm{B}_{5} \mathrm{O}_{4}$ in which BO groups are basically maintained [4], further indicating that bridging S atoms are more energetically favored in $\mathrm{B}_{5} \mathrm{~S}_{4}$ neutral than bridging O in $\mathrm{B}_{5} \mathrm{O}_{4}$ and BS groups are obviously less robust in boron sulfide clusters than BO units in boron oxide counterparts.

### 3.3. ONE-ELECTRON DETACHMENT ENERGIES AND SYMMETRICAL STRETCHING VIBRATIONAL FREQUENCIES

As shown in Table II, B3LYP, OVGF(full), and $\operatorname{CCSD}(\mathrm{T})$ methods produced consistent one-electron detachment energies for $\mathrm{D}_{\infty h} \mathrm{~B}_{2}(\mathrm{BS})_{2}^{-}$and $\mathrm{T}_{\mathrm{d}}$ $\mathrm{B}(\mathrm{BS})_{4}^{-}$anions possible to be characterized in PES
experiments. $D_{\infty h} B_{2}(B S)_{2}^{-}$is predicted to have one strong $X$ band $\left({ }^{3} \sum_{g}^{-}\right)$at 3.09 eV , two closely located weak bands with A $\left({ }^{1} \Delta_{\mathrm{g}}\right)$ at 3.28 eV and B $\left({ }^{1} \sum_{\mathrm{g}}^{-}\right)$at 3.77 eV , and one strong C band $\left({ }^{1} \sum_{\mathrm{g}}^{-}\right)$at 6.19 eV . As the structural relaxation from $\mathrm{D}_{\infty h}$ $B_{2}(B S)_{2}^{-}$to $D_{\infty h} B_{2}(B S)_{2}$ is very small (see Fig. 1), the $X$ band of $B_{2}(B S)_{2}^{-}$is expected to be a sharp peak with close ADE (3.01 eV) and VDE (3.09 eV) values, similar to the situation of $D_{\infty h} B_{2}(B O)_{2}^{-3}$. Besides, the symmetrical stretching vibrations of $\mathrm{B}-\mathrm{B}$ bond at $301 \mathrm{~cm}^{-1}\left(\sigma_{\mathrm{g}}\right), \mathrm{B}=\mathrm{S}$ bond at 1224 $\mathrm{cm}^{-1}\left(\sigma_{\mathrm{g}}\right)$, and $\mathrm{B}=\mathrm{B}$ bond at $1572 \mathrm{~cm}^{-1}\left(\sigma_{\mathrm{g}}\right)$ in neutral $\mathrm{D}_{\infty h} \mathrm{~B}_{2}(\mathrm{BS})_{2}$ (see Table I) are expected to be resolved as vibrational progressions in high resolution PES. It is also possible to observe the symmetrical stretching vibrations of the $D_{\infty h}$ $\mathrm{B}_{2}(\mathrm{BS})_{2}^{-}$anion (Table I) in the hot bands of its PES.

The PES spectrum of $T_{d} B(B S)_{4}^{-}$is predicted to contain broad bands for the reason that significant structural changes are involved from $\mathrm{T}_{\mathrm{d}} \mathrm{B}(\mathrm{BS})_{4}^{-}$to $C_{2} B(B S)_{4}$ (see Fig. 5) when the extra electron is detached. This prediction agrees with the huge energy difference ( $\approx 1.0 \mathrm{eV}$ ) between the calculated $\operatorname{ADE}(5.61 \mathrm{eV})$ and VDE (6.63 eV) at $\operatorname{CCSD}(\mathrm{T})$ level. The symmetrical stretching vibrations of $B-B$ at $309 \mathrm{~cm}^{-1}$ and $B=S$ at $1227 \mathrm{~cm}^{-1}$ and $1300 \mathrm{~cm}^{-1}$ predicted for $C_{2} B(B S)_{4}$ may be resolved in high resolution PES of $\mathrm{T}_{\mathrm{d}} \mathrm{B}(\mathrm{BS})_{4}^{-}$. It is also possible to observe the $\mathrm{B}-\mathrm{B}$ stretching at 298 $\mathrm{cm}^{-1}$ and $\mathrm{B}=\mathrm{S}$ stretching at $1293 \mathrm{~cm}^{-1}$ obtained for $\mathrm{T}_{\mathrm{d}} \mathrm{B}(\mathrm{BS})_{4}^{-}$in the hot bands of its PES. Besides, it should be pointed out that the first VDE $\left({ }^{2} \mathrm{~T}_{2}\right)$ of $\mathrm{T}_{\mathrm{d}} \mathrm{B}(\mathrm{BS})_{4}^{-}$located between 6.3 and 6.6 eV appears to be considerably lower than the corresponding value of $7.8-8.1 \mathrm{eV}$ predicted for $\mathrm{T}_{\mathrm{d}}$ $\mathrm{B}(\mathrm{BO})_{4}^{-}$[7].

## 4. Summary

We have presented an ab initio investigation on the geometrical and electronic properties of $\mathrm{B}_{4} \mathrm{~S}_{2}^{0 /-/ 2-}\left(\mathrm{B}_{2}(\mathrm{BS})_{2}^{0 /-/ 2-}\right)$ and $\mathrm{B}_{5} \mathrm{~S}_{4}^{0 /-}\left(\mathrm{B}(\mathrm{BS})_{4}^{0 /-}\right)$ at different charged states in this work. Both the ground states of linear $D_{\infty h} B_{2}(B S)_{2}^{-}$and $D_{\infty h}$ $B_{2}(B S)_{2}^{2-}$ prove to contain a multiply bonded $B B$ core terminated with two $B S$ groups, while $T_{d}$ $\mathrm{B}(\mathrm{BS})_{4}^{-}$is predicted to possess a perfect tetrahedral $\mathrm{B}^{-}$center directly connected to four BS groups. Their neutrals, on the other hand, possess the planar fan-shaped $\mathrm{C}_{2 \mathrm{v}} \quad \mathrm{B}_{4} \mathrm{~S}_{2}$ and planar kite-
like $C_{2 v} \quad B_{5} S_{4}$ geometries with two bridging $S$ atoms, respectively. Inorganic neutral salts of $\mathrm{B}_{2}(\mathrm{BS})_{2} \mathrm{Li}_{2}$ with $\mathrm{B} \equiv \mathrm{B}$ triple bonds and $\mathrm{B}(\mathrm{BS})_{4} \mathrm{Li}$ with tetrahedral $\mathrm{B}^{-}$centers are predicted possible to be synthesized in experiments.
